Moving Five Sites to Cloudflare Pages — Instructions for ChatGPT

From: Muse AI, at Clay's direction

Date: November 12, 2026

The job: Create the Cloudflare Pages projects for five of Clay's sites, in his Cloudflare account, following the same pattern as the Morning Scroll, which is already moved and live at https://morning-scroll-53x.pages.dev/

Why this piece is yours

Muse's browser cannot pass Cloudflare's sign-in verification (the Turnstile check fails with "There was a problem with verification"), and it failed again under Clay's own hand in the shared browser window. Creating the projects needs a working road into Clay's Cloudflare dashboard. Everything after project creation — reading each build as a reader, fixing standing links, building the old-address forwarding branches, repointing the job instructions — stays with Muse once the project addresses exist.

Already done — do not redo

On GitHub, the "Cloudflare Workers and Pages" app (installation 181362741) is set to "Only select repositories," with these 6 repositories selected and saved: morning-scroll, menu, gilded-pages, report-on-muse-ai-communities, my-daily-review, mogollon-s-hearth-build-page. The GitHub half of the work is finished.

For each repository, in this order

Order: (1) menu, (2) gilded-pages, (3) report-on-muse-ai-communities, (4) my-daily-review, (5) mogollon-s-hearth-build-page.

1. In Clay's Cloudflare account, open Workers & Pages and choose Create.

2. Choose the legacy Pages workflow (the small-print "Continue to Pages" link), then "Get started" beside "Import an existing Git repository."

3. Pick claypnw/<repository> from the list and choose "Begin setup."

4. Setup values: project name = the repository name; production branch = main; framework preset = None; build command = empty; build output directory = leave as it stands. These are plain static sites with their files at the repository root.

5. If the plain project name is already taken, Cloudflare appends a suffix (as it did for the Scroll: morning-scroll became morning-scroll-53x). Record the exact pages.dev address Cloudflare gives, whatever it is.

6. Choose "Save and Deploy" and wait for the Success page.

7. Then open the project's Settings, switch the environment to Preview, open "Branch control," choose "None (Disable automatic branch deployments)," and Save. Preview builds stay off — the free plan counts builds, and this is part of the agreed design.

8. Record the result for that repository before moving to the next: exact project address, whether the first deployment succeeded, and

whether previews are off.

Limits

- Do not touch the morning-scroll project; it is moved, live, and finished.
- Do not change any GitHub Pages settings. The old addresses keep serving until Muse has reader-checked each new build; the switch of each old address to its forwarding branch comes after that, as a separate step.
- Keep "Only select repositories." Never switch the GitHub app to "All repositories."
- No new accounts, no paid plans, no deletions.

Report back

One short report per site, to Clay: the exact pages.dev address, the first deployment's result, and the previews state. When all five stand, Muse takes the next parts: reader checks, standing-link fixes in the repository files and job instructions, forwarding branches, and the old-address switches with Clay.
